2. General descriptions

The hardness is one of the important parameters to determine the mechanical properties of the material, and the hardness test is a way which is used to discriminate and determine the quality of metallic materials or components of the product. The so-called hardness is meant the capability of the material which, under a certain condition, is capable to resist the press-in of another matter which will not produce residual deformation itself. The larger the resisting power is, the higher the hardness will be, and vice versa.

In the course of testing the mechanical properties, hardness measurement is the easiest, most economical, and rapidest method, and is also one of the measures which are used to inspect the quality of the product during manufacturing the machine. As the metallic hardness possesses the mutual corresponding relationship with certain other mechanic properties, hence, most metallic materials may approximately infer their other mechanical properties such as strength, fatigue, creep, wearing and internal damages etc. by determining their hardness.

Following the daily growing development of the industrial and agricultural production as well as the scientific technology, various kinds of different requirements are also demanded to the hardness tester itself, especially it demands high precision in measurement and test, and may carry out various kinds of hardness test for different kinds of materials. Based upon this, the model ISH-BRV Brinell, Rockwell and Vickers hardness tester which is produced by our factory possesses the conditions which fulfill all the above mentioned requirements.

3 The main application and characteristics of the hardness tester

This hardness tester possesses multistage test forces and many kinds of indenters (table 1) which are used to measure and determine the Brinell, Rockwell and Vickers hardness of the metallic materials or test pieces. It is adaptable for determining the hardness of ferrous metals (steel, cast iron pieces, mild steel and quenched steel etc.) and non-ferrous metal (aluminium alloy and

copper alloy etc.), meantime it may also be used to determine the hardness of hard alloy, carburized layer and chemically treated layer. When purchasing, in case the necessary accessory such as surveying microscope is not bought simultaneously, you may also carry out the Brinell, Vickers hardness tests under the cooperation of self -furnished surveying microscope.

The model ISH-BRV Brinell, Rockwell & Vickers hardness tester adopts rotating type load changing mechanism as well as optical measurement indicating system, and the microscopic survey installation is mounted on the body of the apparatus. Hence, it is convenient, sensible and reliable in the loading measuring system, high precision in the shown value, it is widely adaptable to the factory workshop, laboratory, university, college and school as well as scientific research institute.

Table1

Type of test	Test force (N)		Symbol of hardness value	Indenter	Measuring installation	Examples of Measured & tested materials
	Primary test force	Total test force				
Rockwell hardness test	98.07	588.4	HRA	diamond cone indenter	Optical measurement indicating mechanism	hard alloy, carbon carburizing steel
		1471	HRC			quenched steel, adjustable quality steel, hard cast iron
		980.7	HRB			Mild steel, aluminium alloy copper alloy forgeable cast iron
Brinell hardness test	306.5 612.9 1839		HB	φ2.5, φ5mm steel ball indenter	Surveying microscope	Non-ferrous metal cast iron, soft alloy, plastics
Vickers hardness test	294.2 980.7		HV30	diamond angle conical indenter	Surveying microscope	The superficial hardness of metallic alloy carburized layer, small type thin components

Diameter	Ball Diameter D=2.5mm			Ball Diameter D=5mm

4 Technical specification

- 4.1 Primary test force 98.07 N
 4.2 Total test force:
 Rockwell Hardness test 588.4, 980.7, 1471 N
 Brinell hardness test 306.5, 612.9, 1839 N
 Vickers hardness test 294.2, 980.7 N
 4.3 The measuring range of hardness:
 Rockwell hardness test: 20 - 67 HRC
 30 - 100 HRB
 70 - 85 HRA
 Brinell hardness test: 4 - 450 HB
 Vickers hardness test: 14 - 1000 HV
 4.4 Magnifying power of the microscope: 37.5x, 75x
 4.5 The minimum calibrated value of micro-measuring drum wheel:
 when 37.5x, it is 0.004 mm
 when 75x, it is 0.002 mm
 4.6 Height of test piece (max): 180 mm
 4.7 Effective test width: 200 mm
 4.8 Dimension of the outward configuration: 560 x 260 x 760 mm
 4.9 Weight: 90 kg.

5. The installation and adjustment of the hardness tester

The hardness tester which should be under no corrosive gas and no vibrating conditions by horizontally mounted on a stable platform. A Ø70-Ø80 mm hole which is used for the lifting and lowering of a screw rod is drilled at a suitable place on the platform (Fig. 1)

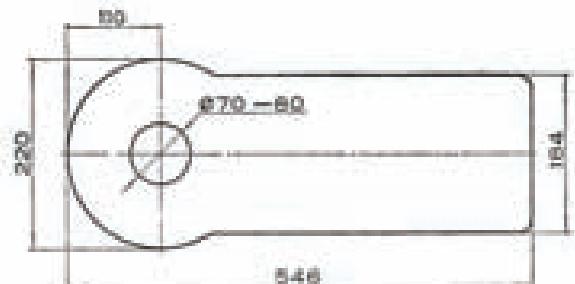

Fig. 1

After the installation of the hardness tester, take away the external white gauze strip of the machine. Remove the dust cover, use gasoline to clean the antirust grease on the lifting and lowering screw rod. After it is dried, coat with certain amount of thin grease for lubrication. Then, unscrew the screws on the upper cover and rear cover respectively, and open the upper cover and rear cover, and unloosen the white gauze strip and rubber band which are inside the machine and take out the oblique shape EPS which is under the screw rod. In the course of operation, pay attention not to touch the optical elements. After completion, close the upper cover in time.

5.1 Installation of weight set

Turn the load adjustment hand wheel to the point of 306N, install the small "0" weight on to the hanging hook which is on the upper part of the suspended lever, then place the other 4 weights according to the sequence of No. 4, 3, 2, 1, respectively from the bottom to the top on to the tray, and observe whether the installation is correct or not.

5.2 Adjustment of the loading speed

Oil contained in the buffer has already been fully drawn out before packaging and leaving the factory, hence, before use, oiling the necessary. Turn the adjustment handle counter clockwise to unloosen the needle valve, open the dust cover plate of the oil filler hole, and push the loading handle backward in the direction, use a needle tube to inject some 50 ml grease. Then pull slowly the loading handle back and forth, repeat in this way many times so as to make the extra grease overflow from the oil filler hole, erase away the overflow grease, then close the dust cover plate.

Adjust the loading speed of the buffer: switch on the power supply, and place the test platform. Turn the loading handle counterclockwise to pull it forward, so as to uplift the screw rod slowly, when the test platform touches the plane of the surveying rod (at that time, the indenter is not mounted yet) uplift the screw rod continuously. When the oblong signal displayed in the reading projecting screen and the target rod gradually uplift. Finally, when the base line and the fixed target rod of the projecting screen coincide, then stop to uplift the screw rod and pull the handle backward by turning the handle in a clockwise direction, at that time, the buffer start its action, the target rod and the signal start to lower gradually, the quickness and slowness of the lowering speed will be adjusted by the buffer adjustment handwheel.

5.3 Adjusting the clarity of the projecting target rod

After switch on the power supply, in case it is discovered that the projecting target rod is dim and not clear, you may rotate the knurled nut in order to make the lamp revolve or uplift, then tighten the knurled nut.

5.4 Installation of the surveying microscope

The surveying microscope which has its internal lighting system is mounted on the left clamping chuck of the machine body by means of its cooperation with the sliding plate test platform, it is capable to test the Brinell and Vickers hardness of the metallic materials.

- 1) When carrying out the Brinell, Vickers hardness test, first, mount the sliding plate test platform on the axial hole of the lifting and lowering screw rod, and fix it by nuts.
- 2) The microscope shall be perpendicularly fixed on the clamping chuck, and install the exterior lighting lampshade which is used for testing the Brinell hardness.
- 3) Use a plug to switch on the power supply, the lamp spigot is situated on the edge of the bakelite cover.
- 4) Based upon the test method, select and mount the objective, generally, for the Brinell hardness test, use 2.5x objective, for the Vickers hardness test, use 5x objective.
- 5) Press several indentations step by step on the standardized test blocks, remove the upper sliding plate under the microscope to look for the indentation. The sliding plate which makes use of the axis hole of the lifting and lowering screw rod as its centre makes circumferential rotation and carefully makes the upper and lower adjustment, align to the focal distance until the indentation appears in the centre of the visual field, then tighten the nut, after completion of the preparation, it is ready for test.

6. Inspection of the shown value precision

After making adjustment for the hardness tester according to the above mentioned methods, then make the shown value precision inspection for the hardness block.

- 6.1 Rockwell hardness test: measure and determine six points on the different positions of the working surface of the standardized Rockwell hardness block, the central distance of two adjacent indentations and the distance from the center of the indentation to the edge of the hardness block shall not be

less than 3 mm. give up the first point, then take the mean value of the rest five points, the difference between the mean value and the standardized hardness block is the shown value error of the hardness tester. The error shall not exceed ± 1 HR.

Within the five points, the difference between the maximum value and the minimum value shall not exceed that specified in the following:

Target rod A is 1.0 HR

Target rod B is 1.2 HR

Target rod C: HRC 35 - 67 is 1.0 HR

HRC 20 - 35 is 1.2 HR

6.2 Brinell hardness test: measure and determine five points which are evenly distributed on the standardized Brinell hardness block, the central distance between two adjacent indentations shall not be less than 4 times the diameter of the indentation. The distance from the center of the indentation to the edge of the hardness block shall not be less than 2.5 times the diameter of the indentation. The measurement for the diameter of each indentation is carried out on two directions which are mutually perpendicular, and take the mean value. The ratio between the difference of the two mutually perpendicular diameter and the shorter diameter shall not be greater than 1%.

Divide the difference between the mean hardness value of the five points measured according to the above mentioned method and the standardized hardness value by the hardness value of the standardized block, this is the shown value error of the hardness tester. When the test force is greater than 1839N, the tolerance allowed is $\pm 3\%$; when the test force is less than 1839N, the tolerance allowed is $\pm 4\%$.

Divide the difference between the maximum value and the minimum value of the hardness values of the five points by the mean hardness value of the 5 points, for the hardness block of $30D^2$, $10D^2$, it shall not exceed 3.5%; for the hardness block of $2.5D^2$, it shall not exceed 5.0%.

Vickers hardness test: measure and determine 5 points which are evenly distributed on the standardized Vickers hardness block, the distance between the center of the two adjacent indentations and the distance from the centre of the indentation to the edge of the hardness block shall not be less than 2.5 times the diagonal length of the indentation. Measure the two diagonals for every indentation and take its mean value.

The ratio between the difference of two diagonals to the shorter diagonal shall not be greater than 2%.

6.3 Divide the difference between the mean hardness value of the 5 points measured and determined according to the above mentioned method and the hardness value of the standardized block by the hardness value of the standardized block, this is the shown value error of the hardness tester. The allowable tolerance is $\pm 2\%$.

Divide the maximum value and the minimum value of the hardness values of the 5 points by the mean hardness value, this is the changeable value of the hardness tester. The allowable tolerance is 2.5% .

The shown value precision of the hardness tester has been adjusted before leaving the factory. In case error produced due to vibration in the course of transportation, the testing personnel shall make suitable adjustment on the basis of understanding its structural principles. Take away the upper cover, if the shown value measured is greater than the marked value of the hardness block, when it is required to lower the hardness reading, then you may use a screw-driver to turn clockwise one degree of the slotted countersunk head screw 2 which is on the spring leaf, meantime tighten one degree of the slotted countersunk head screw 1 by turning it counter clockwise of the optical lever (Fig. 2). Note the rotated degree should be basically conformed. Test the shown value again, until it is adjusted within the specified range of error.

If the shown value measured is less than the standardized block, than the revolving direction of the screw shall be reversed.

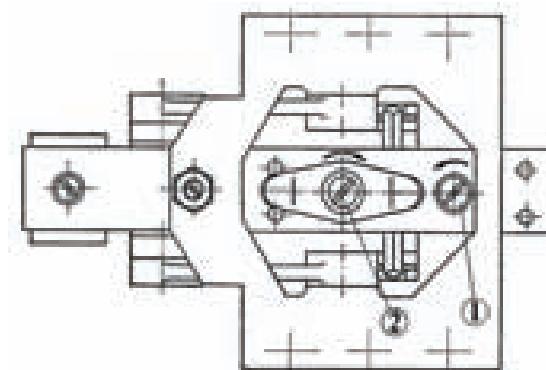

Fig. 2

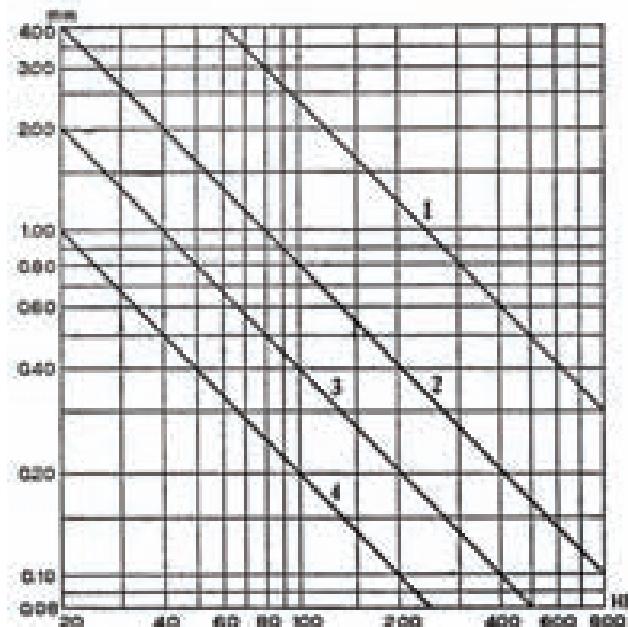

7. The use and maintenance of the hardness tester

7.1 The use of the hardness tester

The preparing work before test:

- 1) Switch on the power supply, based upon the test method, open the switch.
- 2) The surface of the sample to be tested shall be level, bright and clean, it shall not present any outstanding machining traces such as pollutants, oxidized flakes, cracks and pockets etc. The supporting surface of the sample and the test platform shall also keep clean, so as to ensure better closely engaged, the relationship between the minimum thickness of the sample and the hardness may refer to table 2, table 3 and table 4.

Table 2: The relationship between the minimum thickness and hardness HB

Line 1: The diameter of the steel ball is Ø2.5mm.

Test force : 1839N

Line 2: The diameter of the steel ball is Ø2.5mm.

Test force: 612.9N

Line 3: The diameter of the steel ball is Ø2.5mm.

Test force: 306.5N

Line 4: The diameter of the steel ball is Ø2mm.

Test force: 306.5N

Table 3:The relationship between the minimum thickness and hardness HRC, HRB

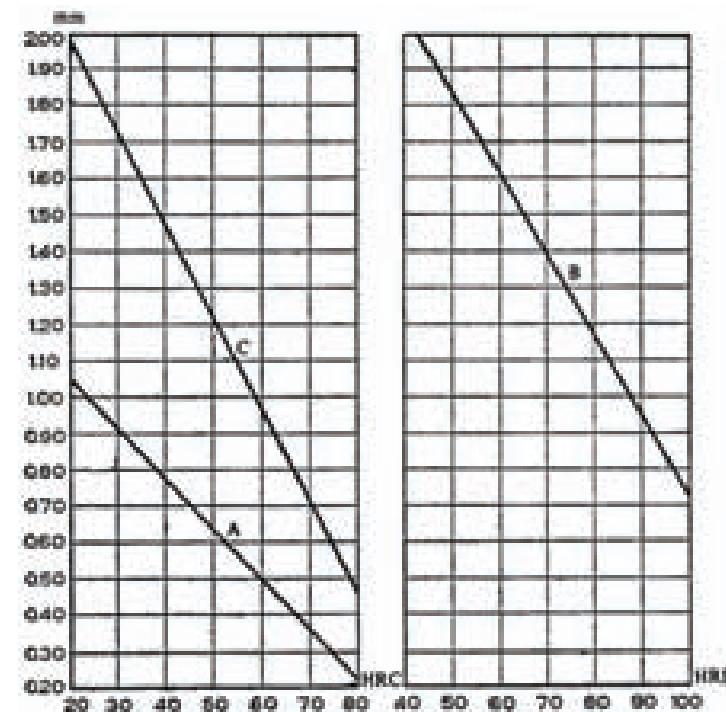

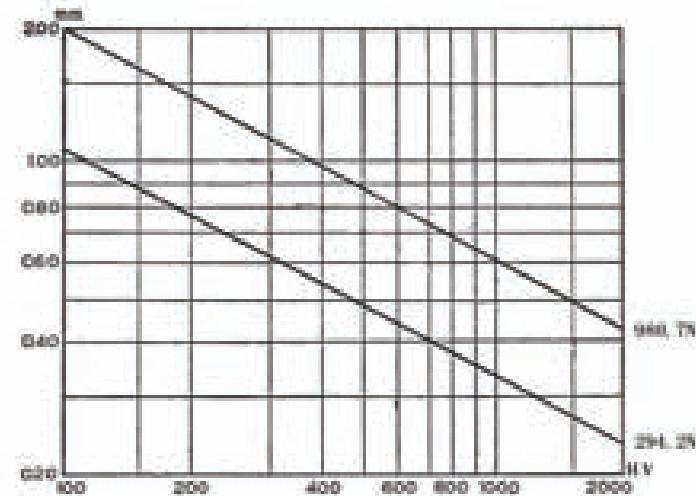

Table 4: The relationship between the minimum thickness and hardness HV

- 3) According to the shape of the test piece, select suitable platform. If the test piece is special shaped, the test platform which is attached together with this hardness tester cannot meet the requirement, then you should base upon the geometric shape of the test piece to design a special test platform by yourself.
- 4) Turn the loading handle of the hardness tester counter clockwise to push it forward, so as to make the load in an unloading state.

Procedures for test:

- (1) Select the indenter according to the hardness test method (table 1). Insert the handle of the indenter into the axial hole of the surveying rod and slightly turn the fixed screw.
- (2) Select the test force according to the hardness test method. Turn the changing handwheel clockwise, in order to make the loading figures needed correspond to the fixed calibrated line.

Note: When the test force used is 294.2N, you should open the rear cover, take away all weights including the small "0" weight.

- (3) Place the test piece reliably on the test platform, then turn the rotating wheel to make the screw rod lift upward, when the test piece is in contact with the indenter, the projecting target rod will lift correspondingly, finally, keep the baseline of the target rod approximately coincide with the fixed line of the projecting screen. The difference allowed may be ± 5 degree value.
- (4) Use the micro-adjustment knob to adjust the zero digit, so as to keep the base line of the target entirely coincide with the projecting screen.. If the knob is turned to the limit position, the two lines are still not able to coincide, then it shall be unloaded, and turn the micro-adjusting knob to the intermediate position, and select another point on the test piece, then repeat the above mentioned operations again.
- (5) Push the loading handle forward by turning it clockwise, during loading, the calibrated line of the target rod which is displayed on the projecting screen is moving up and down, until the target rod stops to lower, then start to compute the load holding time until the load holding time is reached, then pull the handle again to its original position.
- (6) The reading which is the indicating target rod calibrated line on the projecting screen to the fixed target rod line is the Rockwell hardness value of the tested specimen.. Lower the screw rod, make the test piece leave the indenter, move to another position and repeat the above mentioned test.

The Brinell and Vickers hardness test shall, after the completion of the above mentioned procedures, move the upper sliding plate and the test piece together under the microscope, then gradually uplift the screw rod micro-quantitatively, align it to the focal distance, and make the image of the indentation distinct, then measure the diameter of the indentation or the diagonal length of the indentation, next, look over the attached table and obtain the Brinell or Vickers hardness value. When purchasing, the surveying microscope which forms a complete set of the apparatus is not obtained, then you may carry out the survey by means of your own prepared surveying microscope.

The computing method of the surveying microscope against the indentation is as follows:

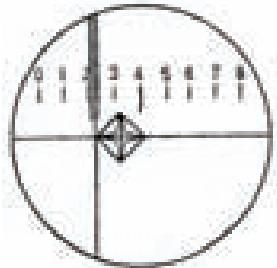

L -- the diameter of the indentation or the diagonal length in mm.
n -- number of division line measured from the indentation (i.e. the difference between the first reading and the second reading).

1 -- the minimum calibrated value of the surveying microscopic drum wheel

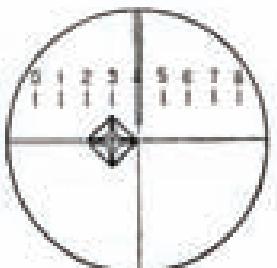

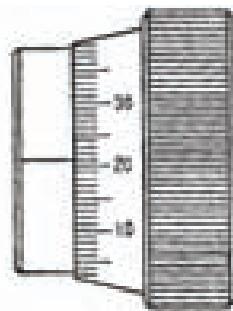

It is 0.004 mm when 2.5x objective is used.

It is 0.002 mm when 5x objective is used.

For instance: Use a 5x objective to measure the Vickers indentation of a 294.2N test force

(a) The first reading is 221 division line.

(b) The second reading is 400 division line.

According to this indentation:

$$L = n \times l = (400 - 221) \times 0.002 = 0.358 \text{ mm.}$$

Look over the attached table, we obtain 434HV

If the Brinell hardness test is carried out, the method of calculation is identical.

Appendix B

Comparison Table Of Indentation Diameter And Brinell Hardness

2. Maintenance of hardness tester and matters to be noted

- 1) The test personnel shall abide by the operating regulations, the hardness tester shall be used and maintained by assigning special person.
- 2) The apparatus shall be in a state of unloading when turning the changing hand wheel.
- 3) In the course of test, when the test piece and indent mutual contact, they shall be slow and stable.
- 4) After the completion of test, you shall keep the apparatus in a state of unloading, covered by a dust cover, the indenter and the hardness block shall be coated with vaseline against rust.
- 5) With the exception of the lifting and lowering part of the screw rod which shall be coated with little amount of lubricant, all of the other parts of the hardness tester shall not be coated or injected with any kind of lubricant.
- 6) When transporting the apparatus, the oil in the buffer shall be drawn off, the transportation shall be carried out with its bottom supported, no lean down to the transverse direction is allowed, it is not allowed to touch the handle during transportation. When transporting, fasten the optical lever by rubber band and take away the weights and suspended lever.

Appendix A

Comparison Table Of Diagonal Indentation Length And Vickers Hardness
